January review and holiday-week plan

NYC Uber + Lyft | Information cutoff: 16 February 2025 | Historical planning simulation

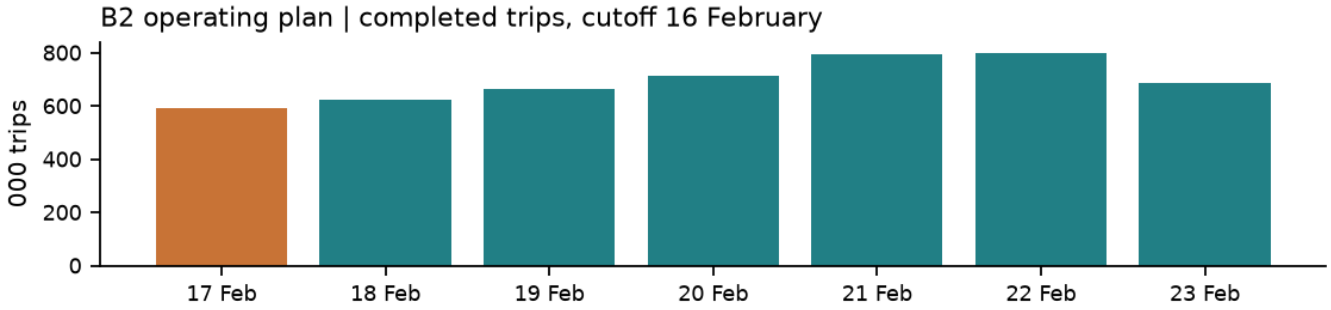
Plan **4,871,468 completed Uber + Lyft trips** for 17-23 February using the two-week same-weekday mean (B2). Treat the MLK adjustment as a holiday scenario, not a proven improvement.

Evidence available at cutoff

In the matched January windows, zone-touching volume was 9.49% below its comparison-based counterfactual (95% day-bootstrap -10.9% to -8.0%). The same zone-versus-outside gap was already -13.85% on 2-4 January, before the fee began, so this design cannot attribute the January gap to the fee. Treat it as a level difference to explain, not a fee effect; a clean estimate needs November-December pre-period data. Lyft had 27.00% of completed Uber + Lyft zone trips in 6-26 January. Its $1.50 offer was future credit, not cash reimbursement. Redemption and campaign incrementality are unmeasured; the January-February share estimate is excluded because it uses data after this decision time.

Plan and action

Use B2 as the provisional baseline, fixed before evaluation. The B3 holiday scenario totals 4,869,000 trips and changes only 17 February. Keep the segment forecasts visible; the four MLK responses differ. Prepare pickup-time monitoring and rain/snow contingency actions. Summer rain coefficients are not February forecast multipliers. No future observed weather or test-week accuracy is used in this plan. Design a targeted $1.50 future-credit experiment with 10% randomized holdout, at least 14 issuance days and redemption follow-up. Decide using measured incremental net contribution per assigned user and guardrails. With assumed $6 contribution and full redemption, break-even is 33.33% uplift on eligible baseline trips; a whole-base 10% threshold requires 30% baseline-trip coverage and a compatible denominator.



What remains unknown

Completed trips exclude failed/cancelled requests. Driver supply, true margin, redemption, retention and causal incrementality are not observed. This simulation assumes trip records were available at cutoff; public TLC monthly releases are retrospective. B2/B3 scenarios are not prediction intervals.
